## Lab – RESTCONF with Python

### Objectives

Part 1: RESTCONF basics in Python

Part 2: Modify interface configuration with RESTCONF in Python

### Background / Scenario

Following up the previous lab activity, in this lab you will learn how to execute the RESTCONF API calls using Python scripts.

### Required Resources

- Python 3.x environment
- Access to a router with the IOS XE operating system version 16.6 or higher.

### Instructions

#### Part 1: RESTCONF in Python

In this part, you will use Python to request a RESTCONF API.

##### Step 1: Import modules and disable SSL warnings.

- In IDLE, click **File > New File** to open IDLE Editor.
- Save the file as **lab 2.5.py**.
- Enter the following commands to import the modules and disable SSL certificate warnings:

```
import json
import requests
requests.packages.urllib3.disable_warnings()
```

The **json** module includes methods convert JSON data to Python objects and vice versa. The **requests** module has methods that will let us send REST requests to a URI.

 2.5\_labv1.py - C:\Users\isidro\Documentos\Unidad 3\2.5\_labv1.py (3.10.7)

```
File Edit Format Run Options Window Help
import json
import requests
requests.packages.urllib3.disable_warnings()
```

##### Step 2: Build the request components.

Create a string variable to hold the API endpoint URI and two dictionaries, one for the request header and one for the body JSON. These are the same tasks you completed in the Postman application.

- Create a variable named **api\_url** and assign the URL (adjust the IP address to match the router's current address).

```
api_url = "https://192.168.56.101/restconf/data/ietf-interfaces:interfaces"
2.5_labv1.py - C:\Users\isidro\Documentos\Unidad 3\2.5_labv1.py (3.10.7)
File Edit Format Run Options Window Help
import json
import requests
requests.packages.urllib3.disable_warnings()

api_url = "https://10.10.20.48/restconf/data/ietf-interfaces:interfaces"
..... ,
```

- e. Create a dictionary variable named **headers** that has keys for **Accept** and **Content-type** and assign the keys the value **application/yang-data+json**.

```
headers = { "Accept": "application/yang-data+json",
            "Content-type": "application/yang-data+json"
          }
```

```
2.5_labv1.py - C:\Users\isidro\Documentos\Unidad 3\2.5_labv1.py (3.10.7)
File Edit Format Run Options Window Help
import json
import requests
requests.packages.urllib3.disable_warnings()

api_url = "https://10.10.20.48/restconf/data/ietf-interfaces:interfaces"

headers = {
    "Accept": "application/yang-data+json",
    "Content-type": "application/yang-data+json"
}
```

- f. Create a Python tuple variable named **basicauth** that has two keys needed for authentication, **username** and **password**.

```
basicauth = ("cisco", "cisco123!")
```

2.5\_labv1.py - C:\Users\isidro\Documentos\Unidad 3\2.5\_labv1.py (3.10.7)

File Edit Format Run Options Window Help

```
import json
import requests
requests.packages.urllib3.disable_warnings()

api_url = "https://10.10.20.48/restconf/data/ietf-interfaces:interfaces"

headers = {
    "Accept": "application/yang-data+json",
    "Content-type": "application/yang-data+json"
}

basicauth = ("developer", "C1sc0l2345")
resp = requests.get(api_url, auth=basicauth, headers=headers, verify=False)
response_json = resp.json()
print(response_json)
```

```
===== RESTART: C:\Users\isidro\Documentos\Unidad 3\2.5_labv1.py =====
{'ietf-interfaces:interfaces': {'interface': [{'name': 'GigabitEthernet1', 'description': 'MANAGEMENT INTERFACE - DON'T TOUCH ME', 'type': 'iana-if-type:ethernetCs
macd', 'enabled': True, 'ietf-ip:ipv4': {'address': [{'ip': '10.10.20.48', 'netmask': '255.255.255.0'}]}, 'ietf-ip:ipv6': {}}, {'name': 'GigabitEthernet2', 'descri
ption': 'Network Interface', 'type': 'iana-if-type:ethernetCsmacd', 'enabled': False, 'ietf-ip:ipv4': {}, 'ietf-ip:ipv6': {}}, {'name': 'GigabitEthernet3', 'descri
ption': 'Network Interface', 'type': 'iana-if-type:ethernetCsmacd', 'enabled': False, 'ietf-ip:ipv4': {}, 'ietf-ip:ipv6': {}}]}}
```

### Step 3: Send the request.

You will now use the variables created in the previous step as parameters for the **requests.get()** method. This method sends an HTTP GET request to the RESTCONF API. You will assign the result of the request to a variable name **resp**. That variable will hold the JSON response from the API. If the request is successful, the JSON will contain the returned YANG data model.

g. Enter the following statement:

```
resp = requests.get(api_url, auth=basicauth, headers=headers, verify=False)
```

The various elements of this statement are:

Element	Explanation
resp	the variable to hold the response from the API.
requests.get()	the method that actually makes the GET request.
api_url	the variable that holds the URL address string
auth	the tuple variable created to hold the authentication information
headers=headers	a parameter that is assigned to the headers variable
verify=False	disables verification of the SSL certificate when the request is made

- h. Save your script and run it. There will not be any output yet but the script should run without errors. If not, review the steps and make sure your code does not contain any errors.

### Step 4: Evaluate the response.

Now the YANG model response values can be extracted from the response JSON.

- i. The response JSON is not compatible with Python dictionary and list objects so it is converted to Python format. Create a new variable called **response\_json** and assign the variable **resp** to it adding the **json()** method to convert the JSON. The statement is as follows:

```
response_json = resp.json()
```

- j. You can verify that your code returns the JSON in the IDLE Shell by temporarily adding a print statement to your script, as follows:

```
print(response_json)
```

- k. Save and run your script. You should get output similar to the following although your service ticket number will be different:

```
>>>
RESTART: B:/DevNetAcad PS-E/Workshops/ETW3 Model Driven Programmability/Python Files with Solutions/idle/lab 2.9.py
({'ietf-interfaces:interfaces': {'interface': [{'name': 'GigabitEthernet1', 'type': 'iana-if-type:ethernetCsmacd', 'enabled': True, 'ietf-ip:ipv4': {}, 'ietf-ip:ipv6': {}}, {'name': 'Loopback1', 'description': 'WHATEVER', 'type': 'iana-if-type:softwareLoopback', 'enabled': True, 'ietf-ip:ipv4': {'address': [{'ip': '2.2.2.2', 'netmask': '255.255.255.0'}]}, 'ietf-ip:ipv6': {}}, {'name': 'Loopback2', 'description': 'NEWBUTSAME', 'type': 'iana-if-type:softwareLoopback', 'enabled': True, 'ietf-ip:ipv4': {}, 'ietf-ip:ipv6': {}}, {'name': 'Loopback99', 'description': 'WHATEVER99', 'type': 'iana-if-type:softwareLoopback', 'enabled': True, 'ietf-ip:ipv4': {'address': [{'ip': '99.99.99.99', 'netmask': '255.255.255.0'}]}, 'ietf-ip:ipv6': {}}, {'name': 'Loopback100', 'description': 'TEST1', 'type': 'iana-if-type:softwareLoopback', 'enabled': True, 'ietf-ip:ipv4': {'address': [{'ip': '100.100.100.100', 'netmask': '255.255.255.0'}]}, 'ietf-ip:ipv6': {}}]}}})
>>>
```

- l. To prettify the output, use the **json.dumps()** function with the “indent” parameter:

```
print(json.dumps(response_json, indent=4))
```

- m. Save and run your script. If you experience errors, check the code again.

## Part 2: Modify interface configuration with RESTCONF in Python

### Step 1: Create the Python HTTP PUT request

In this part, you will use Python to request a RESTCONF API with a PUT method to create or modify existing configuration.

### Step 2: Import modules and disable SSL warnings.

- n. In IDLE, click **File > New File** to open IDLE Editor.
- o. Save the file as **lab 2.5 part2.py**.
- p. Enter the following commands to import the modules and disable SSL certificate warnings:

```
import json
import requests
requests.packages.urllib3.disable_warnings()
```

The **json** module includes methods convert JSON data to Python objects and vice versa. The **requests** module has methods that will let us send REST requests to a URI.

### Step 3: Build the request components.

Create a string variable to hold the API endpoint URI and two dictionaries, one for the request header and one for the body JSON. These are the same tasks you completed in the Postman application.

- q. Create a variable named **api\_url** and assign the URL that targets the **Loopback99** interface.

```
api_url = "https://192.168.56.101/restconf/data/ietf-  
interfaces:interfaces/interface=Loopback99"
```

- r. Create a dictionary variable named **headers** that has keys for **Accept** and **Content-type** and assign the keys the value **application/yang-data+json**.

```
headers = {  
    "Accept": "application/yang-data+json",  
    "Content-type": "application/yang-data+json"  
}
```

- s. Create a Python tuple variable named **basicauth** that has two keys needed for authentication, **username** and **password**.

```
basicauth = ("cisco", "cisco123!")
```

- t. Create a Python dictionary variable **yangConfig** holding the YANG data to create new interface Loopback99 (you use here the dictionary data from the Postman lab before, be aware that the JSON's boolean **true** is in Python **True** with capital "T"):

```
yangConfig = {  
    "ietf-interfaces:interface": {  
        "name": "Loopback99",  
        "description": "WHATEVER99",  
        "type": "iana-if-type:softwareLoopback",  
        "enabled": True,  
        "ietf-ip:ipv4": {  
            "address": [  
                {  
                    "ip": "99.99.99.99",  
                    "netmask": "255.255.255.0"  
                }  
            ]  
        },  
        "ietf-ip:ipv6": {}  
    }  
}
```

## Step 4: Send the PUT request.

You will now use the variables created in the previous step as parameters for the **requests.put()** method. This method sends an HTTP PUT request to the RESTCONF API. You will assign the result of the request to a variable name **resp**. That variable will hold the JSON response from the API. If the request is successful, the JSON will contain the returned YANG data model.

- u. Enter the following statement:

```
resp = requests.put(api_url, data=json.dumps(yangConfig), auth=basicauth,  
headers=headers, verify=False)  
if (resp.status_code >= 200 and resp.status_code <= 299):  
    print("STATUS OK: {}".format(resp.status_code))  
else:  
    print("Error code {}, reply: {}".format(resp.status_code, resp.json()))
```

The various elements of this statement are:

Element	Explanation
resp	the variable to hold the response from the API.
requests.get()	the method that actually makes the GET request.
api_url	the variable that holds the URL address string
data	the data to be sent to the API endpoint
auth	the tuple variable created to hold the authentication information
headers=headers	a parameter that is assigned to the headers variable
verify=False	disables verification of the SSL certificate when the request is made
resp.status_code	The HTTP status code in the API Request reply

v. Save your script and run it.

```
>>>
RESTART: B:/DevNetAcad PS-E/Workshops/ETW3 Model Driven Programmability/Python Files with Solutions/idle/lab 2.9 part2.py
STATUS OK: 201
>>> |
```

w. Verify using the IOS CLI that the new Loopback99 interface has been created (sh ip int brief).

x. Modify the code to delete the interface Loopback99.

y. What changes were applied to the code to delete the interface Loopback99?

```
2.5_labv2.py - C:\Users\isidro\Documents\Unidad 3\2.5_labv2.py (3.10.7)
File Edit Format Run Options Window Help

import json
import requests
requests.packages.urllib3.disable_warnings()

api_url = "https://10.10.20.48:443/restconf/data/ietf-interfaces:interfaces/interface=Loopback99"

headers = {
    "Accept": "application/yang-data+json",
    "Content-type": "application/yang-data+json"
}
basicauth = ("developer", "Cisc012345")

yangConfig = {
    "ietf-interfaces:interface": {
        "name": "Loopback99",
        "description": "isidro lab2.5",
        "type": "iana-if-type:softwareLoopback",
        "enabled": True,
        "ietf-ip:ipv4": {
            "address": [
                {
                    "ip": "192.168.20.210",
                    "netmask": "255.255.255.0"
                }
            ]
        },
        "ietf-ip:ipv6": {}
    }
}

resp = requests.put(api_url, data=json.dumps(yangConfig), auth=basicauth, headers=headers, verify=False)
if (resp.status_code >= 200 and resp.status_code <= 299):
    print("STATUS OK: {}".format(resp.status_code))
else:
    print("Error code {}, reply: {}".format(resp.status_code, resp.json()))
```

en este ejercicio se realizó la misma consulta que en laboratorio anterior con postman pero ahora con una interfaz de solo código de Python utilizando el idle con el protocolo REQUEST y los modelos Yang para la salida de la ejecución.

### ¿Qué es RESTCONF?

El propósito primordial de RESTCONF es permitir que las aplicaciones web (que usan el protocolo HTTP) accedan a un dispositivo de red para la compra de datos de configuración y estado.

RESTCONF se divide primordialmente en 2 capas: capa de contenido y capa de protocolo.

Capa de contenido: define una recolección de objetos para ser operados, definidos en lenguaje YANG, y distingue entre datos de administración y de configuración.

Capa de protocolo: Usa de manera directa el protocolo HTTP (+TLS) para conceder funcionalidades diversas del contenido.

### Interacción entre NETCONF y RESTCONF

NETCONF es un protocolo para mandar configuraciones a los dispositivos de red. Posibilita a los usuarios centrarse en los datos de configuración en vez de en los comandos de configuración.

No obstante, diferentes dispositivos necesitan diferentes construcciones de configuración.

Esta diferencia se resuelve por medio de la definición del modelo yang, que es un lenguaje de modelado de datos. Los usuarios solamente deben mejorar la configuración solicitada en el modelo yang para configurar los accesorios subyacentes.

El papel de RESTCONF está en la capa de servicio web. Conforme con la URL, rellena la información del modelo yang para crear la composición de configuración del dispositivo que corresponde. Después, según esto, se puede crear el XML para mandar la solicitud al dispositivo que corresponde para su configuración

### análisis del script:

se ve el script realizado para importar lo que es los módulos json, requests para realizar o ejecutar llamadas ala API RESTCONF mediante scripts de Python.

json incluye métodos que convierten datos JSON en objetos de Python y viceversa. El módulo tiene métodos que nos permitirán enviar solicitudes REST a una URI.

Realizamos una variable de diccionario denominada headers que tenga claves para aceptar y tipo de contenido y asigne a las claves el valor application/yang-data+json.

utilizamos las variables creadas en el paso anterior como parámetros para el método request.get(). Este método envía una solicitud HTTP GET a la API RESTCONF. Que asignará el resultado de la solicitud a un nombre de variable resp. Esa variable contendrá la respuesta JSON de la API. Si la solicitud tiene éxito, el JSON contendrá el modelo de datos YANG devuelto

realizamos una variable de diccionario de Python `yangConfig` que contenga los datos de YANG para crear una nueva interfaz `Loopback99` (utilice aquí los datos de diccionario del laboratorio de Postman antes, tenga en cuenta que el valor booleano de JSON está en Python `True` con "T" mayúscula).

También utilizamos las variables creadas en el paso anterior como parámetros para el método `request.put()`. Este método envía una solicitud HTTP PUT a la API RESTCONF. Asignará el resultado de la solicitud a un nombre de variable `resp`. Esa variable contendrá la respuesta JSON de la API. Si la solicitud tiene éxito, el JSON contendrá el modelo de datos YANG devuelto.
